Software Write Up: Summer Camp Lunch Package Registration

The Summer Camp Lunch Package Registration system will be a web application that allows parents and guardians to order lunches for campers attending summer camp at Tucker Road Ice Rink. I chose this project because Tucker Road Ice Rink is my other job, so I am familiar with how the café prepares and organizes lunches for summer campers. The camp operates four days per week for three weeks, giving each camper 12 camp days. The system will organize registrations, calculate costs, and provide accurate daily meal totals to the café.

Parents can purchase one week of lunches, which includes four days, half of the camp period, which includes six days, or the full camp period, which includes 12 days. Only one lunch can be ordered for each selected day. The available choices are chicken tenders, fries, and a drink for \$11; cheese pizza, fries, and a drink for \$11; or pepperoni pizza, fries, and a drink for \$12. The system will calculate the total price based on the number and types of meals selected.

The users will include parents or guardians, camp staff, café employees, and an administrator. Parents will enter the camper's information, allergies or dietary restrictions, selected package, camp dates, and daily meal choices. They will also be able to track the number of orders placed, completed orders, and days remaining in camp. Camp staff can review each camper's lunch status, whereas café employees can view how many of each meal must be prepared for a specific day. The administrator will manage registrations, meal options, prices, dates, and order statuses.

The user interface will include a registration form, package selection page, daily meal selection page, confirmation page, and parent dashboard. Staff will have a dashboard for searching registrations and updating orders. The café dashboard will display the total number of chicken tender, cheese pizza, and pepperoni pizza meals required each day. The interface will be simple so that people with different levels of technology experience can use it.

HTML and CSS will create and style the application pages, whereas JavaScript will validate forms and calculate order totals. Python and Flask will manage the application logic, process registrations, and connect the interface to the database. Flask is suitable because it supports forms, multiple pages, and database operations while remaining manageable for a student project. SQLite will store camper details, guardian information, allergies, dates, package limits, meal selections, prices, and order statuses. It is appropriate because it connects directly to Flask without requiring a separate database server. GitHub will store the project document and code while tracking changes throughout development.
